CP468 Assignment1 Missionaries and Cannibals

By Group 4 ZZ-TW-ML-YC

Abstraction

For convenience, in the remainder, each abbreviation has its own meaning:

Abbreviation	Meanning
$\mathbf{M}$	missionary
$\mathbf{C}$	cannibal
N	number of $\mathbf{M}$ or $\mathbf{C}$ (the same)
B	number of seats in boat
ml	number of $\mathbf{M}$ on left side
mb	number of $\mathbf{M}$ in boat
mr	number of $\mathbf{M}$ on right side
cl	number of $\mathbf{C}$ on left side
cb	number of $\mathbf{C}$ in boat
cr	number of $\mathbf{C}$ on right side
pos	position of boat, left side: 1, right side: 0
(ml, cl, pos)	one state when the boat is empty and on side pos, $ml\mathbf{M}$ and $cl\mathbf{C}$ are on the left side
$L(mb, cb)$	carry $mb\mathbf{M}$ and $cb\mathbf{C}$ to left side
$R(mb, cb)$	carry $mb\mathbf{M}$ and $cb\mathbf{C}$ to right side

Reality constraints

Each number must be non-negative and less than the total number:

$$0 <= ml, mb, mr, cl, cb, cr <= N$$

$$0 <= mb, cb <= B$$

$$ml + mb + mr == cl + cb + cr == N$$

The boat can not across the river without someone in it:

$$0 < mb + cb <= B$$

Security constraints

Whether on left, right or in boat, the number of $\mathbf{M}$ should not less than that of $\mathbf{C}$:

$$ml == 0 || ml >= cl$$

$$mb == 0 || mb >= cb$$

$$mr == 0||mr >= cr$$

Initial State

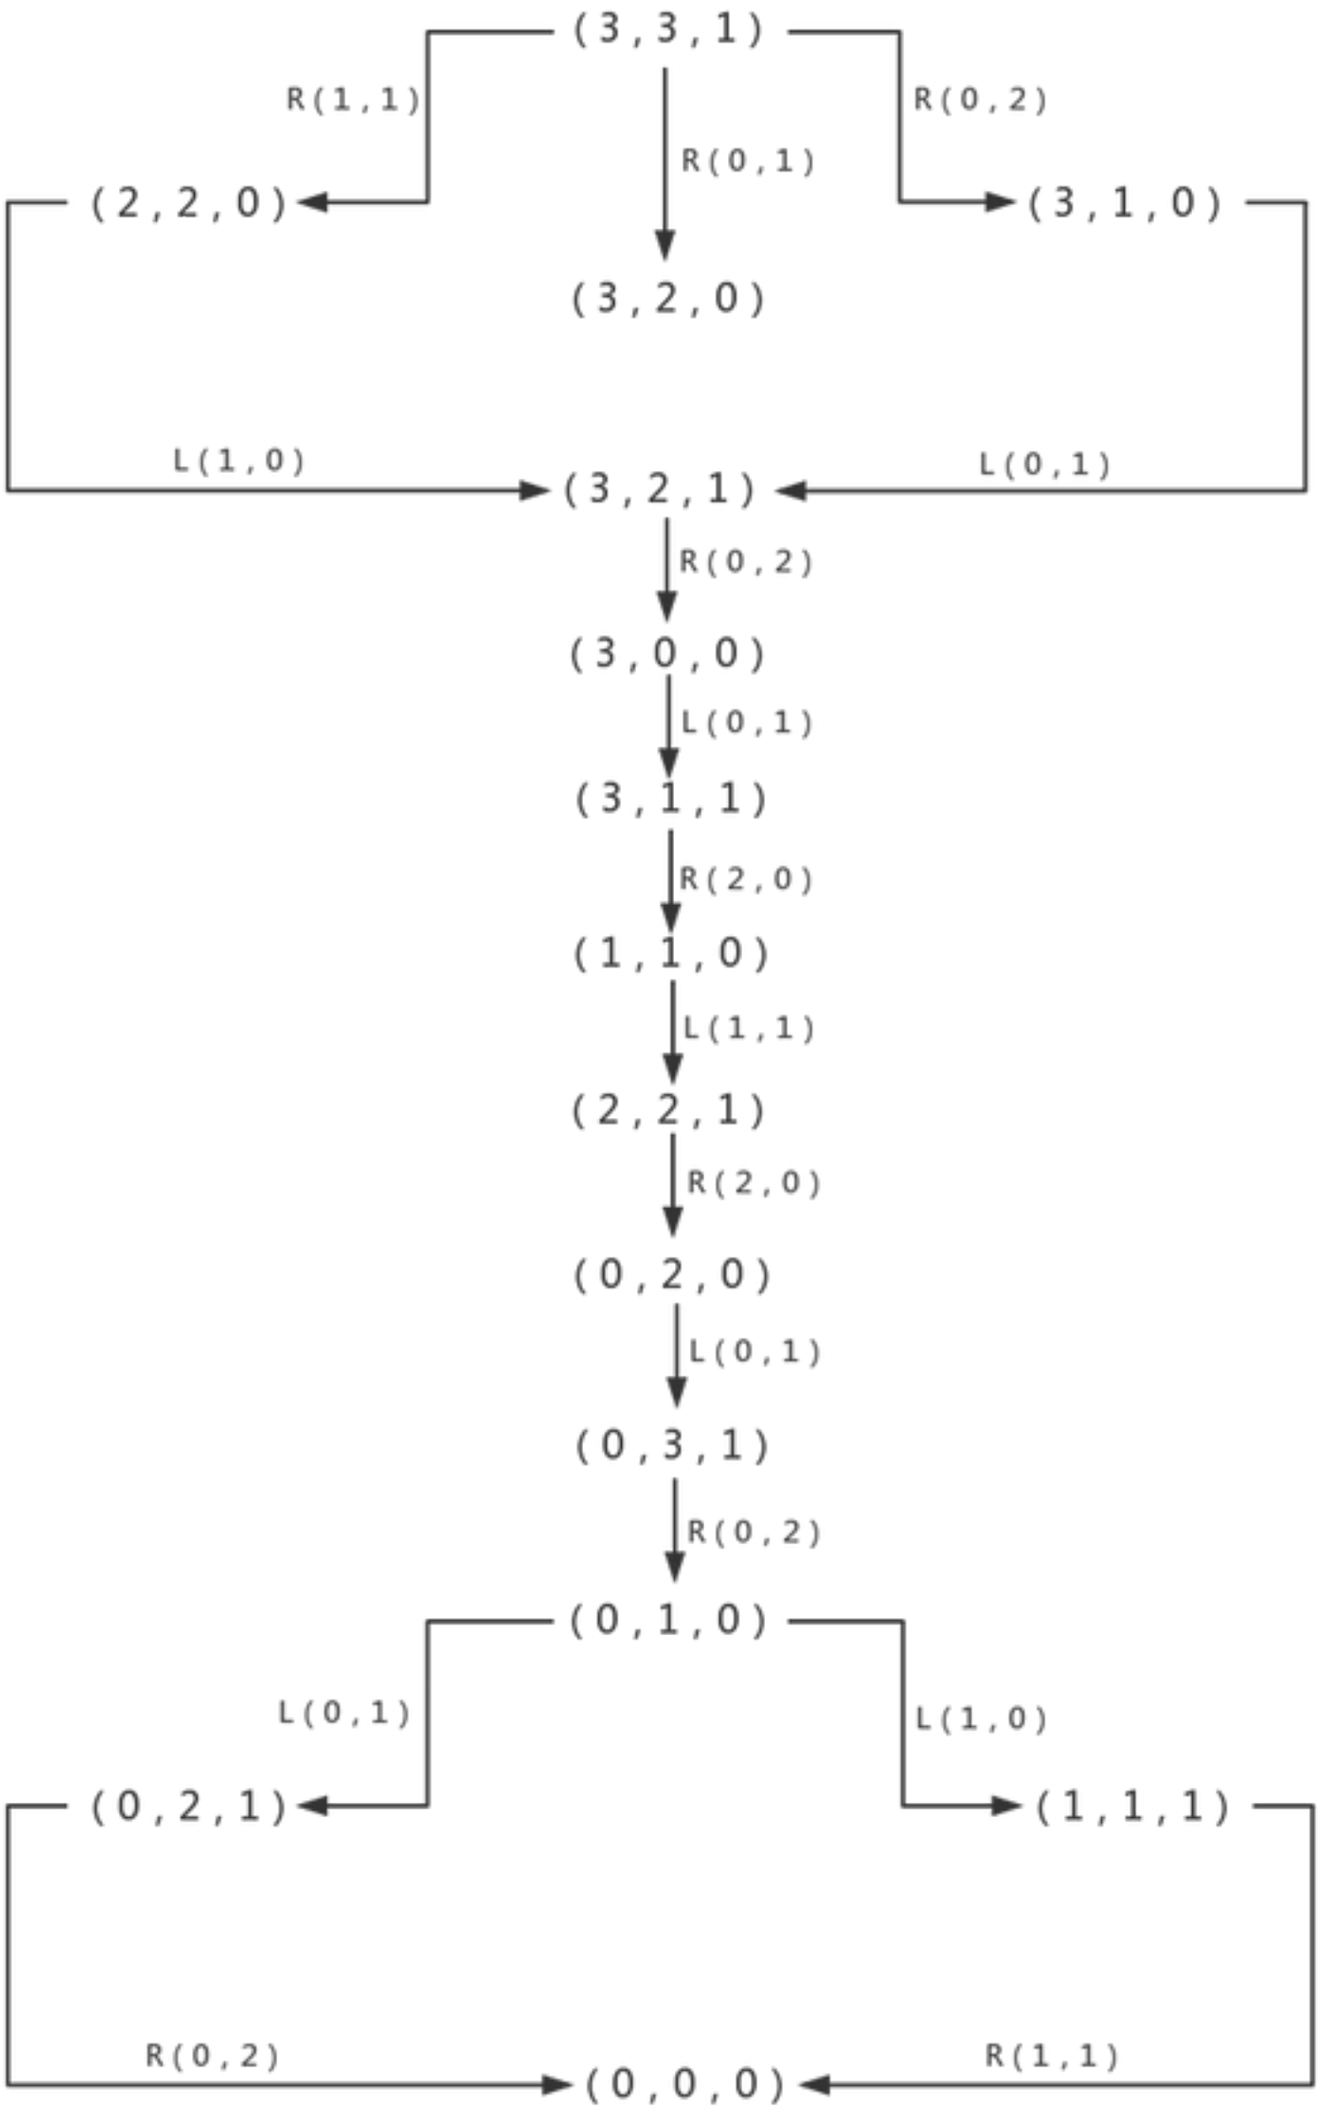
$N\mathbf{M}$ and $N\mathbf{C}$ are on one side, let's say left side, with a boat at the same side, described as $(N, N, 1)$.

Goal State

$N\mathbf{M}$, $N\mathbf{C}$ and the boat are on the right side, described as $(0, 0, 0)$.

State Space

Take $N == 3, B == 2$ as an example, below is the complete state space graph:



There are 10 states and $16 * 2 = 32$ transitions in total. For short we just show half of transitions:

Transitions

$Result\Big((3,3,1), R(1,1)\Big) = (2,2,0)$
$Result\Big((3,3,1), R(0,1)\Big) = (3,2,0)$
$Result\Big((3,3,1), R(0,2)\Big) = (3,1,0)$
$Result\Big((2,2,0), L(1,0)\Big) = (3,2,1)$
$Result\Big((3,1,0), L(0,1)\Big) = (3,2,1)$
$Result\Big((3,2,1), R(0,2)\Big) = (3,0,0)$
$Result\Big((3,0,0), L(0,1)\Big) = (3,1,1)$
$Result\Big((3,1,1), R(2,0)\Big) = (1,1,0)$
$Result\Big((1,1,0), L(1,1)\Big) = (2,2,1)$
$Result\Big((2,2,1), R(2,0)\Big) = (0,2,0)$
$Result\Big((0,2,0), L(0,1)\Big) = (0,3,1)$
$Result\Big((0,3,1), R(0,2)\Big) = (0,1,0)$
$Result\Big((0,1,0), L(0,1)\Big) = (0,2,1)$
$Result\Big((0,1,0), L(1,0)\Big) = (1,1,1)$
$Result\Big((0,2,1), R(0,2)\Big) = (0,0,0)$
$Result\Big((1,1,1), R(1,1)\Big) = (0,0,0)$

Path Cost

Path cost increased by one each time when the boat cross the river.

Algorithm Analysis

We considered two algorithms for this problem:
iterative deenpening depth-first search(IDS) and iterative deepening a* search(IDA*).

	IDS	IDA*
complete	Y	Y
optimal	Y	Y
time	$O(b^d)$	$O(b^d)$
space	$O(bd)$	$O(bd)$

IDS and IDA* are both complete in that they will continue searching until find a solution or exhaust all states. They are optimal in that the cost is increasing during iteration, in other words, the first solution found must cost least.
IDS and IDA* are also the same in structure: outside is a iteration of limit and inside is a recursion of search function.
But IDS uses $g(n)$ (cost from start state to current state n) as limit, IDA* uses $f(n) = g(n) + h(n)$ (global estimated cost) instead.
Moreover, IDS does DFS within the limit from one child state; while IDA* will expand at the child state with the minimum value of $f(n)$.

Another thing worth talking is the selection of hueristic function of IDA*.

//TODO 启发函数的选择

Implementation in Java

Source code can be find here: https://github.com/BIOTONIC/MissionariesAndCannibals

Test.java	State.java	Action.java	IDS.java	IDAStar.java
call two algorithms	store state's info & provide functions related to state	use two lists to store all valid arrangements of $\mathbf{M}$ and $\mathbf{C}$ on boat	IDS algorithm	IDA* algorithm

Below is the output of two algorithms when $N == 3$ and $B == 2$. Solutions of two algorithms are the same because they traverse all actions of a given state by the same sequence provided by Action.java. One difference is that IDA*'s limit starts directly from 4.

```
iterative deepening depth-first search
try depth limit 1
try depth limit 2
try depth limit 3
try depth limit 4
try depth limit 5
try depth limit 6
try depth limit 7
try depth limit 8
try depth limit 9
try depth limit 10
try depth limit 11
optimal solution found
step 1: (3,3,1) => (0,2)
step 2: (3,1,0) <= (0,1)
step 3: (3,2,1) => (0,2)
step 4: (3,0,0) <= (0,1)
step 5: (3,1,1) => (2,0)
step 6: (1,1,0) <= (1,1)
step 7: (2,2,1) => (2,0)
step 8: (0,2,0) <= (0,1)
step 9: (0,3,1) => (0,2)
step 10: (0,1,0) <= (0,1)
step 11: (0,2,1) => (0,2)

iterative deepening a star search
try depth limit 4
try depth limit 5
try depth limit 6
try depth limit 7
try depth limit 8
try depth limit 9
try depth limit 10
try depth limit 11
optimal solution found
step 1: (3,3,1) => (0,2)
step 2: (3,1,0) <= (0,1)
step 3: (3,2,1) => (0,2)
step 4: (3,0,0) <= (0,1)
step 5: (3,1,1) => (2,0)
step 6: (1,1,0) <= (1,1)
step 7: (2,2,1) => (2,0)
step 8: (0,2,0) <= (0,1)
step 9: (0,3,1) => (0,2)
step 10: (0,1,0) <= (0,1)
step 11: (0,2,1) => (0,2)
```

Both algorithms are able to solve N missionaries, N cannibals and B seats problems. Below is the ouput when $N == 7$ and $B == 4$:

```
step 1: (7,7,1) => (0,4)
step 2: (7,3,0) <= (0,2)
step 3: (7,5,1) => (0,4)
step 4: (7,1,0) <= (0,2)
step 5: (7,3,1) => (4,0)
step 6: (3,3,0) <= (1,1)
step 7: (4,4,1) => (2,2)
step 8: (2,2,0) <= (1,1)
step 9: (3,3,1) => (2,2)
step 10: (1,1,0) <= (1,1)
step 11: (2,2,1) => (2,2)
```

//TODO 何时有解无解

The remainder is the source code. Download it from github if you want to run and test it.

```
// Test.java
// call two algorithms

public class Test {
    public static void main(String[] args) {
        new IDS(7, 4, 1000); // N=7 B=4 upperLimit=1000
        new IDAStar(3, 2, 1000); // N=3 B=2 upperLimit=1000
    }
}
```

```
// State.java
